

# TECHNICAL DATASHEET

# **ELECTRA WLP 4478**

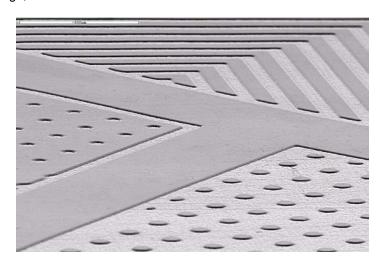

Aqueous Developable
WAFER-LEVEL PACKAGING
PHOTODIELECTRIC

# **PRODUCT SUMMARY**

**Electra WLP 4478** is a liquid, i-line photodielectric designed for wafer-level packaging applications. The product may be spin-coated onto glass and silicon wafers at thicknesses ranging from 5 – 40um.

# Electra WLP 4478 performance properties include:

- Fast exposing less than 250mJ/cm² for sub-10um layers
- Resolution capability to 15 um track and gap
- Optimum properties achieved by 150°C cure
- Processed by aqueous chemistry
- Low Odour
- · Ambient storage, 12 month shelf life

WLP 4478

**VIPRA** 

**ELECTRA-D'OR** 

## PROCESSING REQUIREMENTS

## **Process Environment**

Electra WLP 4478 is a high definition, negative-working photopolymer. It is sensitive to extraneous near-UV light, and excessive temperature and humidity. It is recommended that all application processing steps and inspection should be done in a controlled, clean-room environment:

Lighting: Yellow Light, wavelength > 450nm

Temperature: 20 to 25°C Relative Humidity: 30 - 70%

## **Product Description**

WLP 4478 is a 2-pack epoxy-acrylate system. The main component is WLP 4478/A The hardener is WLP 4815.

The mix ratio of WLP 4478/A to WLP 4815 is 83: 17 w/w

### **Product Mixing**

To obtain optimum results, it is important that mixing of the ink and hardener is done thoroughly. For quantities of less than approximately 200g, adequate mixing may be achieved manually, for example by rounded spatula, in 3 5 minutes.

Motor driven devices are strongly recommended for larger quantities, but are generally less efficient at mixing-in product from the sides of containers. A mixing period of 15 to 20 minutes is recommended. High-shear mixers will cause air entrainment and should not be used.

Moderate vacuum may be used to remove micro-air bubbles prior to spin-coating; however, some solvent will be lost during vacuum-degassing which will result in viscosity increase. For example, a vacuum of 67 kPa (500mm Hg) can result in viscosity increase of 4% per hour for mixed product at 22°C.

# **Product Rheology**

WLP 4478 is essentially a Newtonian fluid over a wide shear rate range, as demonstrated below. This property is important for even distribution of the photodielectric during spin-coating.

Shear Rate, 1/s	Viscosity*, mPa.s
0.2	5940
2.0	5940
20	5890
200	5710

<sup>\*</sup> Viscosity measurement conditions:

Cone and plate instrument, 40mm/4° truncated cone, operating in controlled shear rate mode at 22°C

## Pot Life and Mixed Viscosity Increase

The viscosity of the mixed product increases with time ( see below) but the product remains processable for up to 8 days when stored at a temperature no greater than 22°C. Generally, reducing storage temperature increases the mixed product pot life. The increasing viscosity of the mixed product as a function of time may be used to advantage when spin-coating.

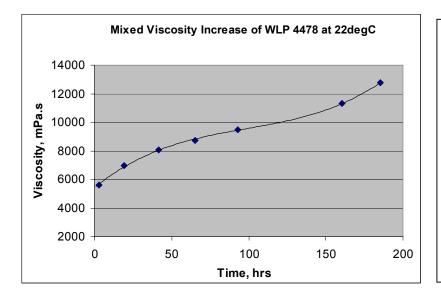

Figure 1 shows the rate of increase of viscosity over eight days for mixed product stored at 22-23°C:

**ELECTRA-D'OR** 

www.electrapolymers.com

Figure 1.

Viscosity measurement conditions: Cone and plate instrument, 40mm/4° truncated cone, operating at controlled shear rate 2/s at 22°C

## **Surface Preparation**

To obtain the optimum adhesion of Electra WLP 4478, the substrate should be free from surface contaminants such as grease, oxides and fingerprints.

#### Silicon and Glass Wafers

An adhesion promoter is generally necessary to ensure a reliable bond. A number of proprietary silane coatings are available for this purpose. The manufacturer's recommendations should be followed, including surface pre-treatment and method of application.

Typically, the wafer is flooded with a dilute (1-3%) solution of a compound such as aminopropyltriethoxysilane, methacryloxypropyltrimethoxysilane, or vinyltriethoxysilane. The wafer is then spun dry. A baking or other conditioning period may be advisable before applying the photodielectric.

### Copper Laminate

An adhesion promoter is not normally required on copper, as long as the surface has been freshly prepared. Suitable techniques are:

- a. Brush Pumice (grade 3F or 4F)
- b. Jet Pumice (grade 3F or 4F)
- c. Wet Brush (grade 320 grit)
- d. Chemical (oxide preferred)

When using mechanical cleaning, surface roughness should be in the range of 2 to 4microns for optimum adhesion. For high resolution work, reduced surface roughness may be beneficial.

The metal surface should be dried before coating. Five minutes at 80°C is adequate for plain surfaces, but drilled or perforated surfaces may require a longer period.

Pre-cleaned copper panels should be coated within four hours, to minimize oxide build-up.

WLP 4478

VIPRA

# Coating

# **Spin Coating**

The increasing viscosity of the mixed product on aging (see above) enables it to be spin-coated at a wide range of thicknesses. The values shown below may be used as a guide, for spin-coat periods of 1 - 2 minutes:

Viscosity, mPa.s	Spin Speed, rpm	Coating Thickness, um
6000	6000	5 - 6
10,500	2500	21
	3000	18
	3500	16
13,000	1500	40
	2000	30
	2500	24

## **Screen Printing**

Printing conditions will vary depending upon the mode of use of the product. The conditions stated below are suitable where WLP 4478 is being used as a conventional soldermask and a deposit of approximately 20um is being applied.

### Screen Printing Parameters

Screen mesh: 34T Polyester
 Tension: 13-17N/cm²

o Squeegee 60-80 Shore hardness, rounded edge

Angle 75°
 Printspeed <3 m/min</li>
 Snap-off 4mm

# **Drying**

Electra WLP 4478 can be dried by batch, conveyorised or IR convection ovens. Drying times will depend on the coated thickness and type of drying equipment.

For air convection ovens and coatings of 5 – 10um, a typical drying cycle is 10 minutes at a board surface temperature of 75°C.

20 – 40um coatings will typically require a drying period of 20-30 minutes at 75°C.

Total drying period should not exceed 50 mins at 75°C, or 35 mins at 80°C.

Coatings should be cooled to room temperature (20°C) prior to exposure, to prevent variations in photosensitivity, and artwork marking / sticking.

#### **Imaging**

High resolution images may be achieved using a suitable phototool in conventional UV equipment.

The product is sensitive to light in the range of 340 to 420nm. Exposure units with iron-doped mercury lamps in the 3 to 10 KW range are recommended. Exposure frame temperatures in excess of 30°C should be avoided, in order to prevent photo-tool sticking. Good vacuum (better than 0.6 bar recommended) is important during exposure for optimum cross linking of the soldermask, and for intimate contact between the phototool and resist.

Exposure times will depend on the type of equipment used and the resist thickness and to some extent on the required resolution. Reducing exposure energy can significantly reduce line growth, particularly for thin films. Typical exposure energies are as follows:

www.electrapolymers.com

Dried Coating Thickness, um	UV Exposure Energy Range, mJ/cm <sup>2</sup>	Approx. Resolution ( Track and Gap) Achievable
5 - 10	70 - 250	10-20um
10 - 20	180 - 350	20um
20 - 30	300 - 400	25um
30 - 40	350 - 450	35um

A Stouffer 21 Step Wedge will assist with UV- energy setting. For optimum film performance, a clear copper step 9 – 11 should be targeted. This should be achieved in combination with a developer breakpoint in the range 30 – 50% (see below).

Electra WLP 4478 contains a photofugitive dye which produces a visual contrast between exposed and nonexposed resist.

### Developing

Hold time between exposing and developing should not exceed 24 hours. For highest resolution work, hold time should be minimised.

Electra WLP 4478 may be developed by sodium or potassium carbonate solutions in the range 1.0 – 1.3% w/v. at a temperature of 28 - 35°C.

Acceptable working pH range is 11.4 (fresh developer solution) to 10.6, although pH should be maintained, by carbonate solution replenishment, above pH 10.8 for high resolution work. Note however that a combination of high pH, high developing temperatures (35+°C) and solution concentrations in excess of 1.3% can degrade the surface of the coating.

Developing time will depend on the above parameters, on resist thickness and on the equipment used. A spray pressure of at least 2 bar is recommended to ensure clean developing.

A break point of 50% (ie, bare substrate revealed at half total developer dwell time) is generally recommended, although high resolution work may require a slightly longer developing time.

A water rinse at 10 - 20°C and spray pressures of 1.5 to 2.0 bar should be applied.

A deionized water rinse after mains water rinsing and the use of a hot air turbine drier will help to reduce drying marks..

Antifoam solution may be necessary in the developer to prevent frothing.

#### **Thermal Curing**

Maximum chemical and thermal resistance is obtained using a thermal curing time of 60 minutes at 150°C. This will normally equate to a total curing cycle time of 75 to 90 minutes. There is some latitude to reduce the temperature at the expense of increased cure time, for temperature sensitive applications; but full cure is unlikely to be achieved below 135°C.

There is a reduction of film thickness of between 5 – 10% when comparing developed-only and thermally cured coatings.

Electra WLP 4478 can also be cured using infra-red curing equipment. Temperature settings and lines speeds will depend on the type of equipment being used.

A blanket UV cure of 1.5 – 3.0 joules per cm<sup>2</sup> carried out after developing, will generally increase the hardness of the product. This increased hardness may be beneficial through soldering and defluxing.

www.electrapolymers.com

Additionally, blanket UV cure will reduce resist thickness loss between developing and final (thermal) cure, and aid resist performance if a low imaging exposure had been used to obtain maximum resolution.

#### Resist Removal

Errors in the product application process may require the resist to be stripped. The imaged (but not fully-cured) resist can be removed in an aqueous solution of 5% potassium hydroxide at a temperature of 50 to 60 °C. Alternatively, the imaged resist may be removed by a variety of ketone, glycol and glycol ester solvents.

Fully cured resist has high chemical resistance, and is not readily attacked. However, soaking layers in hot organic base solution, or in an aggressive solvent mixture such as methylene chloride / butyrolactone, will soften the resist and facilitate its removal.

Always consult suppliers' MSDS, particularly when using aggressive chemistries.

# **Illumination of Working Areas**

Electra WLP 4478 is sensitive to strong white light. It is recommended that the working areas be illuminated with yellow fluorescent lamps, such as Phillips type 1.2m TL-D36W-16. Windows should be coated with a non bleachable yellow film which is not transparent to wave lengths below 450nm. Plexiglas type yellow 303 is equally suitable.

#### Storage Conditions

For optimum long term storage, Electra WLP 4478 should be held in the unmixed state in a dry and cool environment (30 to 70% RH at a temperature of between 5 and 20°C).

The minimum shelf life of the product under these conditions is 12 months from date of manufacture.

Pot-life of mixed Components A+B: 8 Days at a temperature of 22° C

## **Shipping Conditions**

Electra WLP 4478 is a stable product in the unmixed state and does not require refrigeration for long-distance seafreight or trucking purposes but should be stored under recommended condition once delivered.

## **Product Characteristics and Final Properties**

The following product characteristics and performance levels are expected, but these data do not constitute a specification:
